What is Trio?

What is Trio?

Trio is an open-source automated insulin delivery system (OS-AID) for iOS based on the OpenAPS algorithm with adaptations for Trio.

This system considers your user-entered settings, carbohydrates, and historical insulin use to automate insulin delivery to reduce the time spent managing your diabetes.

Before starting with Trio, you should evaluate all your closed-loop options, including:

- Commercial systems
- Other open-source applications
  - Loop
  - AndroidAPS

🚧 Documentation Under Construction 🚧

This documentation is being released while still under construction. Please keep in mind the following information:

- Any page with a ✏️ indicates the information has not yet been updated. The information on those pages should not be referenced at this time.
- We welcome assistance with proofreading, editing, and updating the information in this documentation. If you would like to contribute to the documentation, please submit issues or PRs here
- New educational videos are coming soon.

To use Trio, you are required to build the application from the source code. This does not require substantial technical know-how but is a time-consuming process. You may need several sessions to complete your first build.

Upon installation, you will follow an onboarding wizard in the app to configure your settings optimally. We strongly recommend using the New User Setup Guide as you walk through onboarding so you are able to easily reference any additional information you may need.

If you find yourself stuck, the community is here to help on Discord or Facebook.

Contribution

Trio is built by a volunteer community. If you are interested in helping as a programmer, you can contribute to the Trio or Trio-Oref code base. Trio is written in Swift, and the Trio-Oref/OpenAPS algorithm is currently written in JS and is in the process of being converted into Swift.

You can also provide support in online support groups by sharing your own success and troubleshooting common errors.
